

The thesis „Physiotherapy of soft hand weavings disorders resulting from postneuritic over freight" is bent on weightiest consequence of over freight of hand flexor sinews, which is rupture and on one of weightiest consequences of accident states of sinews, which is transcision. Rupture and transcision of hand flexor sinews is cured in a similar surgical way, by suture and coincident is as well the subsequent alteration postoperative care. The aim of my diploma work that ties on my baccalaureate work, is rounded up from the expert literature, especially the foreign one, researching the information of possibilities and meaning of rehabilitative care in those specific problems and these information then virtually compare with the choice study sample inmates. I hereto directed everything, so as I could in the end answers the questions: what meaning has rehabilitation and whether there is any universal method that could be applied in the appropriate manner. In its experimental parts the diploma work succeeded to prove the evidence, that the rehabilitation holds irreplaceable space in therapy of hand flexor sinews after effected sutures. The study proves the obvious difference in results between the group that passed the rehabilitation therapy and the group that the rehabilitation didn't undergo. The tracked pyramidal method of the therapy of the hand flexor sinews, confirmed my notions about this till this time best more elaborated and the most appropriate method. The results reached by the pyramidal method really clearly surpassed those gained by other methods.
