

The objective of this paper is to find standard of knowledges about providing first aid in common people. Since I found out, that question of first aid doesn't appeal to people and they don't know the most fundamental elements of first aid, I decided to do research on this subject and to find whether cases which I met are solitary or are usual by majority of inhabitants. And subsequently to devise possibilities to improve standart knowledge of first aid.

The collection of data was led through technology of questionnaire, which I distributed in to the different types of public, so that result would have the biggest value.

The questions concerned an experience of people with first aid and their information about this problem.

The questions were formulated as close with possibility of selection from two or more answers, half-closed questions and open questions where the respondents completed with their job and telephone number for ZZS.

The advantage of this collection of data was a contact with respondents and possibility of discussion. Majority of respondents wanted to know, where they made mistakes and why their answer wasn't correct. 300 questionnaires were distributed and 216 was completed.

The results of investigation are supporting fact, that public don't show any concern about first aid and therefore they are not informed sufficiently and so they are not able to provide first aid in sufficient form.
