

Oncology issue is intertwined with all branches of medicine. With regard to tumor bladder, I took the impression that they are, especially in articles intended for lay public, a bit neglected and perhaps a bit overshadowed by more frequent, not urologic, cancers (lung, breast and colorectal cancer). Unjustly. The incidence and mortality of this disease in our country and the world continues to rise, and thus of the disease

rise was also interested, especially in prevention. That's why I've topic "Risk factors for bladder cancer" has chosen as its theme thesis.

The first chapter deals with a brief summary of the anatomy and histology bladder and the mechanism of carcinogenesis. The second chapter deals on the overall issue of bladder tumors. These two parts are mainly to understand the following text, so I tried does not go into greater detail. In the last chapter, I deal with issues of risk itself factors. On many of these studies are still ongoing. However, the proven carcinogens, such as those resulting from smoking or aromatic amines from industrial production should certainly be taken into account in the form of the largest and the best preventive measures.
