

Abstract:

Name: First aid knowledge of graduating students

Aims: The aim of this bachelor thesis is to determine the level of first aid knowledge among high school seniors and to compare the differences between different types of schools.

Methods: This is a theoretical and empirical work. The research methods included a quantitative questionnaire survey which was conducted among final year students of selected secondary schools. The survey includes questions focusing on key aspects of first aid. The data was analyzed to determine success rates and identify statistically significant differences between student groups.

Results: The results of the survey showed that on average, medical school and grammar school students achieve higher success rates in first aid tests than secondary vocational school students.

Summary: It can be concluded that increasing awareness and knowledge of first aid among students is essential to increase the overall level of preparedness for emergency situations. I recommend the inclusion of more practical exercises and simulations in school curricula, especially in vocational secondary schools, to reduce the differences in first aid knowledge between different types of schools. I also recommend that teaching materials be regularly updated in line with the latest recommendations of professional organisations.
