

My diploma thesis is divided into two parts, theoretical and practical. The former consists of three parts. Firstly, I was dealing with the history and etiology of cerebral palsy. Secondly, Vojta's method is being described as the main method in the therapy of cerebral palsy. Thirdly, kinesiological stages are characterised in the development of a child since her birth till her one year. Practical part deals with the case reports of three people. The first one represents an analysis of a female, who suffered from cerebral palsy in her childhood. The second deals with the analysis and photos of a young male, where I didn't expect from any anomaly on his kinetics and its function in his childhood and adulthood. The third one represents the diagnosis of central coordination disorder during Vojta's method and the evaluation of the child's kinesiological development in 60 different time periods. Finally, I am dealing with the facts which I found out during my research.
